[Google](#) has set up a new search engine specifically for source code: [/* Code Search */](#).

Important difference with their normal search engine is that it allows restricting your search by programming language, license and filename and package. I have not been able to figure out how to use 'package' yet, but the others are pretty clear. For example: `AtomContainer`
`license: LGPL lang: java` should do it. The search results show filenames, licenses and programming languages:

Alternatively, you can use [Koders](#), which is a source code search engine too. It has been around for quite some time now, and shows the copyright notice too. Additionally, Koders offers a [plugin for Eclipse](#) which adds a search 'view' which will show the HTML from the website in an editor window inside Eclipse.
